OF

ARNON GAT

**FAST HEATING AND COOLING APPARATUS  
FOR SEMICONDUCTOR WAFERS**

Field of the Invention

5

The present invention is generally directed to a method and apparatus for rapidly heating and rapidly cooling semiconductor wafers in a thermal processing chamber. More particularly, the present invention is directed to a rapid thermal processing apparatus that includes a cooling device for cooling semiconductor wafers rapidly after the wafers have been heated.

10

Background of the Invention

15

A thermal processing chamber as used herein refers to a device that rapidly heats objects, such as semiconductor wafers. Such devices typically include a substrate holder for holding a semiconductor wafer and a thermal energy source, such as a light source that emits light energy for heating the wafer. During heat treatment, the semiconductor wafers are heated under controlled conditions according to a preset temperature regime. For monitoring the temperature of the semiconductor wafer during heat treatment, thermal processing chambers also typically include temperature sensing devices, such as pyrometers, that sense the radiation being emitted by the semiconductor wafer at a selected band of wavelengths. By sensing the thermal radiation being emitted by the wafer, the temperature of the wafer can be calculated with reasonable accuracy.

20

25

30

35

In alternative embodiments, instead of or in addition to using radiation sensing devices, thermal processing chambers can also contain thermocouples for monitoring the temperature of the wafers. Thermocouples measure the temperature of objects by direct contact.

Many semiconductor heating processes require a wafer to be heated to high temperatures so that various chemical and physical reactions can take place as the wafer is fabricated into a device. During 5 rapid thermal processing, which is one type of processing, semiconductor wafers are typically heated by arrays of lights to temperatures, for instance, from about 400°C to about 1,200°C, for times which are typically less than a few minutes. During these 10 processes, one main goal is to heat the wafers as uniformly as possible.

More particularly, in the past, semiconductor wafers were heated according to a predetermined heating cycle. For instance, the wafers were 15 typically heated from an initial temperature to a desired temperature at a very fast heating rate. The wafers were then maintained at the desired temperature for a time sufficient for desired processes to take place. For instance, during these heating cycles the 20 wafers can be annealed or various coatings and films can be deposited onto the wafers, such as oxide films.

In order to complete the heating cycle, the light sources are switched off and the wafers were allowed to cool after being maintained at a desired 25 temperature for a predetermined amount of time. In general, the wafers were allowed to cool naturally by simply removing or turning off the heating source. In particular, the wafers would cool by the loss of energy through radiation from a hot body. The amount 30 of energy that is lost from the wafer is proportional to the difference between the temperature of the wafer and the temperature of the surrounding atmosphere. Consequently, during these processes, the cooling rate 35 of the wafers is relatively fast at high temperatures and then slows down exponentially as the temperature

of the wafer decreases.

Recently, emphasis has been placed upon forming integrated circuits having thinner and more uniform layers that are more efficient and require less power to operate. In this regard, recent focus has turned to not only more precisely forming coatings and films in thermal processing chambers but also on reducing the length of time it takes to complete a heating cycle in the chamber. Unfortunately, however, conventional methods for cooling wafers in thermal processing chamber have frustrated these objectives.

For instance, as described above, conventional methods for cooling wafers in thermal processing chambers have a tendency to greatly increase the time it takes to complete a heating cycle within the chamber in that the wafers are cooled relatively slowly. Further, during this slow cooling phase of the cycle, unwanted chemical and physical reactions can occur which can adversely affect the electrical properties of coatings and films formed on the semiconductor wafer.

As such, a need currently exists for an improved apparatus and process for cooling wafers in rapid thermal processing chambers. In particular, a need currently exists for a rapid thermal processing chamber that is capable of actively cooling semiconductor wafers very rapidly after the wafers have been heated.

#### Summary of the Invention

The present invention recognizes and addresses the foregoing disadvantages and others of prior art constructions and methods.

Accordingly, it is an object of the present invention to provide an improved method and apparatus for heat treating objects, such as semiconductor

wafers.

Another object of the present invention is to provide an improved apparatus for heat treating semiconductor wafers that is capable of cooling the wafers rapidly.

Still another object of the present invention is to provide an improved apparatus for heat treating semiconductor wafers that includes a cooling device that actively cools the wafers after the wafers have been heated.

These and other objects of the present invention are achieved by providing an apparatus for heat treating semiconductor wafers during the process of producing integrated circuits. The apparatus can be used for various operations such as for annealing wafers after an ion implantation step, or for constructing or annealing coatings and films on semiconductor wafers, such as those made from conductive materials, insulators, and semiconductive materials. The apparatus includes a thermal processing chamber adapted to contain semiconductor wafers. A substrate holder can be contained within the thermal processing chamber for holding and rotating the wafers. For heating the wafers, a heat source can be placed in communication with the thermal processing chamber. The heat source can be, for instance, a plurality of lamps which emit thermal light energy.

In accordance with the present invention, the apparatus further includes a cooling device located proximate to the substrate holder for selectively cooling semiconductor wafers contained in the thermal processing chamber. The cooling device includes a cooling member which defines at least one cooling channel for circulating a cooling fluid, such as a

liquid. In particular, by circulating a cooling fluid through the cooling member, the cooling device maintains a relatively low temperature that is then used to cool semiconductor wafers through convection and conduction.

5 Preferably, the cooling device of the present invention is only used to cool the semiconductor wafers at selected times, such as after the wafers have been heated to a predetermined maximum 10 temperature. For instance, in one embodiment, the cooling device can include a movement mechanism for moving the cooling device between an engagement position and a non-engagement position. In the engagement position, the cooling device is placed 15 adjacent to and possibly in direct contact with the semiconductor wafer held on the substrate holder for cooling the wafer. In the non-engagement position, on the other hand, the cooling device is spaced a determined distance from the semiconductor wafer and 20 does not substantially cool the wafer or interfere with the wafer while the wafer is being heated. Alternatively, instead of the cooling device being 25 movable towards and away from the substrate holder for selectively cooling the wafer, the substrate holder can be movable towards and away from the cooling device.

In a further embodiment of the present invention, 30 the cooling device can be stationary and can include one or more gas passages for circulating a gas therethrough. In particular, the gas passages can be designed such that a gas flowing through the passages is cooled by the cooling fluid being circulated 35 through the cooling device. Once cooled, the gas can then be directed towards and can contact a semiconductor wafer held on the substrate holder for

cooling the wafer. The cooling gas can be, for instance, molecular nitrogen or helium. In order to only cool the wafer at selected times, the flow of cooling gases through the cooling device can be stopped and started when desired.

5 In one preferred embodiment of the present invention, the apparatus further includes a temperature sensing device for monitoring the temperature of a semiconductor wafer contained within 10 the thermal processing chamber. A controller can be placed in communication with the temperature sensing device and can also be configured to control the heat source and the cooling device. Specifically, the controller can receive temperature information from 15 the temperature sensing device and, based on such information, can automatically control the heat source and the cooling device for heating and cooling wafers according to a predetermined temperature cycle.

20 In controlling the heat source, for instance, the controller can be used to increase or decrease the amount of thermal energy being emitted onto the semiconductor wafer. In controlling the cooling device, on the other hand, the controller can be 25 configured to control the movement of the cooling device and/or the flow of the cooling fluids in and out of the cooling device.

Other objects, features and aspects of the present invention are discussed in greater detail below.

30 Brief Description of the Drawings

A full and enabling disclosure of the present invention, including the best mode thereof, directed to one of ordinary skill in the art, is set forth more particularly in the remainder of the specification, 35 which makes reference to the appended figures in

which:

5       Figure 1 is a cross-sectional view of one embodiment of an apparatus for heat treating semiconductor wafers in accordance with the present invention;

10      Figure 2 is a cross-sectional view of one embodiment of a cooling device that may be used in a thermal processing chamber in accordance with the present invention;

15      Figure 3 is a cross-sectional view of the cooling device illustrated in Figure 2;

20      Figure 4 is an alternative embodiment of a cooling device that may be used in a thermal processing chamber in accordance with the present invention; and

25      Figure 5 is a time and temperature graph illustrating the difference between conventional heating cycles and heating cycles that may be used in a thermal processing chamber made in accordance with the present invention.

30      Repeat use of references characters in the present specification and drawings is intended to represent same or analogous features or elements of the invention.

25      Detailed Description of the Preferred Embodiments

35      It is to be understood by one of ordinary skill in the art that the present discussion is a description of exemplary embodiments only, and is not intended as limiting the broader aspects of the present invention, which broader aspects are embodied in the exemplary construction.

40      In general, the present invention is directed to an apparatus and method for heating and cooling wafers in a thermal processing chamber. For heating semiconductor wafers, the thermal processing chamber

can contain conventional heating sources, such as a plurality of lamps that emit radiant energy. In accordance with the present invention, the apparatus further contains a cooling device that actively cools the semiconductor wafers after the wafers have been heated. The cooling device can take on various forms and can function in different manners. For instance, in one embodiment, the cooling device can include a cooling member which receives a cooling fluid for maintaining the cooling device at a lower temperature. The cooling device can further include a mechanism that is configured to cool the wafers only at selected times.

Various advantages and benefits are achieved through the apparatus and process of the present invention. For instance, through the use of the cooling device, the time it takes to complete a heating cycle in an apparatus of the present invention is substantially reduced. By reducing the length of time it takes to complete a heating cycle, thermal processing chambers made in accordance with the present invention are particularly well adapted to cause effective annealing of damage and activation of ion implanted impurities in the silicon, to form ultrathin coatings and films on semiconductor wafers, and to anneal thin films, conductive or insulating, which were previously deposited on semiconductor wafers. The thermal processing chamber of the present invention is also capable of forming very uniform coatings and films with improved electrical properties. In particular, according to the present invention, semiconductor wafers can be cooled very rapidly which "freezes" the chemical and physical reactions at a high temperature that are occurring in the chamber. In other words, cooling the wafers very

rapidly prevents and inhibits unwanted and undesired chemical and physical reactions to occur during the relatively slow cool down phase of the heat cycle.

Referring to Figure 1, a system generally 10 made in accordance with the present invention for heat treating a wafer made from a semiconductive material, such as silicon, is illustrated. System 10 includes a processing chamber 12 adapted to receive substrates such as a wafer 14 for conducting various processes. As shown, wafer 14 is positioned on a substrate holder 15 made from a thermal insulating material such as quartz. Chamber 12 is designed to heat wafer 14 at very rapid rates and under carefully controlled conditions. Chamber 12 can be made from various materials, including metals. For instance, chamber 12 can be made from stainless steel, brass or aluminum.

When chamber 12 is made from a heat conductive material, preferably the chamber includes a cooling system. For instance, as shown in Figure 1, chamber 12 includes a cooling conduit 16 wrapped around the perimeter of the chamber. Conduit 16 is adapted to circulate a cooling fluid, such as water, which is used to maintain the walls of chamber 12 at a relatively low temperature.

Chamber 12 can also include a gas inlet 18 and a gas outlet 20 for introducing a gas into the chamber and/or for maintaining the chamber within a preset pressure range. For instance, a gas can be introduced into chamber 12 through gas inlet 18 for reaction with wafer 14 in order to form, for example, oxide coatings, conductive layers, etc. Once processed, the gas can then be evacuated from the chamber using gas outlet 20.

Alternatively, an inert gas can be fed to chamber 12 through gas inlet 18 for preventing any unwanted or

undesirable side reactions from occurring within the chamber. In a further embodiment, gas inlet 18 and gas outlet 20 can be used to pressurize chamber 12. A vacuum can also be created in chamber 12 when desired, 5 using gas outlet 20 or an additional larger outlet positioned beneath the level of the wafer.

During processing, substrate holder 15, in one embodiment, can be adapted to rotate wafer 14 using a wafer rotation mechanism 21. Rotating the wafer 10 promotes greater temperature uniformity over the surface of the wafer and promotes enhanced contact between wafer 14 and any gases introduced into the chamber. It should be understood, however, that besides wafers, chamber 12 is also adapted to process 15 optical parts, films, fibers, ribbons, and other substrates having any particular shape.

A heat source or heating device generally 22 is included in communication with chamber 12 for heating wafer 14 during processing. Heating device 22 20 includes a plurality of lamps 24, such as tungsten-halogen lamps. As shown in Figure 1, lamps 24 are placed above wafer 14. It should be understood, however, that lamps 24 may be placed at any particular 25 location. Further, additional lamps could be included within system 10 if desired.

The use of lamps 24 as a heat source is generally preferred. For instance, lamps have much higher heating and cooling rates than other heating devices, such as electrical elements or conventional furnaces. 30 Lamps 24 create a rapid isothermal processing system that provide instantaneous energy, typically requiring a very short and well controlled start up period. The flow of energy from lamps 24 can also be abruptly stopped at any time. As shown in the figure, lamps 24 35 are equipped with a gradual power controller 25 that

can be used to increase or decrease the radiant energy being emitted by any of the lamps.

In order to monitor the temperature of wafer 14 during the heating process, in this embodiment, 5 thermal processing chamber 12 includes plurality of radiation sensing devices generally 27. Radiation sensing devices 27 include a plurality of optical fibers or light pipes 28 which are, in turn, in communication with a plurality of corresponding light 10 detectors 30. Optical fibers 28 are configured to receive thermal energy being emitted by wafer 14 at a particular wavelength. The amount of sensed radiation is then communicated to light detectors 30 which generate a usable voltage signal for determining the 15 temperature of the wafer which can be calculated based, in part, on Planck's Law. In one embodiment, each optical fiber 28 in combination with a light detector 30 comprises a pyrometer.

In general, thermal processing chamber 12 can 20 contain one or a plurality of radiation sensing devices. In a preferred embodiment, as shown in Figure 1, thermal processing chamber 12 contains a plurality of radiation sensing devices that measure the temperature of the wafer at different locations. 25 Knowing the temperature of the wafer at different locations can then be used to control the amount of heat being applied to the wafer.

During the process of the present invention, 30 system 10 should be designed such that optical fibers 28 only detect thermal radiation being emitted by wafer 14 and not detect radiation being emitted by lamps 24. In this regard, system 10 includes a filter 32 which prevents thermal radiation being emitted by lamps 24 at the wavelength at which light detectors 30 35 operate from entering chamber 12. Filter 32 also

5 serves to isolate lamps 24 from wafer 14 and prevent contamination of the chamber. Filter 32 as shown in Figure 1 can be a window positioned between chamber 12 and heat source 22 and can be made from, for instance, fused silica or quartz. In an alternative embodiment, each lamp 24 can be covered by a separate filter.

10 Besides using radiation sensing devices, other temperature sensing devices may be used in the system of the present invention. For instance, one or more thermocouples may be incorporated into the system for monitoring the temperature of the wafer at a single location or at a plurality of locations. The thermocouples can be placed in direct contact with the wafer or can be placed adjacent the wafer from which 15 the temperature can be extrapolated.

20 System 10 further includes a system controller 50 which can be, for instance, a microprocessor. Controller 50 receives voltage signals from light detectors 30 that represent the radiation amounts being sampled at the various locations. Based on the signals received, controller 50 is configured to calculate the temperature of wafer 14 at different 25 locations.

30 System controller 50 as shown in Figure 1 can also be in communication with lamp power controller 25. In this arrangement, controller 50 can determine the temperature of wafer 14, and, based on this information, control the amount of thermal energy being emitted by lamps 24. In this manner, instantaneous adjustments can be made regarding the conditions within reactor 12 for processing wafer 14 35 within carefully controlled limits.

35 In one embodiment, controller 50 can also be used to automatically control other elements within the system. For instance, controller 50 can be used to

control the flow rate of gases entering chamber 12 through gas inlet 18. As shown, controller 50 can further be used to control the rate at which wafer 14 is rotated within the chamber.

5 In accordance with the present invention, as shown in Figure 1, system 10 further includes a cooling device 60 positioned in thermal processing chamber 12. As shown, in this embodiment, cooling device 60 is located below semiconductor wafer 14 and is mounted on a base 62. Cooling device 60 is for 10 actively and rapidly cooling wafer 14 at selected times with the thermal processing chamber, particularly after the wafer has been heated to a predetermined processing temperature.

15 In accordance with the present invention, cooling device 60 can be constructed in various ways and can include different mechanisms for cooling wafers. Referring to Figures 2 and 3, one embodiment of a cooling device made in accordance with the present invention is illustrated. In this embodiment, cooling device 60 includes cooling member 64 having a plate-like shape. Cooling member 64 includes cooling channels 66 which are designed to receive the flow of a cooling fluid therethrough. For instance, cooling member 64 can be placed in communication with a cooling fluid source, such as a water source, which supplies a cooling fluid to cooling channel 66. The cooling fluid maintains the temperature of cooling member 64 at a relatively low temperature thus 20 allowing cooling device 60 to actively cool semiconductor wafer 14 through the direct exchange of thermal energy between the wafer and the cooling member.

25

30

35

As described above, preferably cooling device 60 only cools the wafer at selected times during the

course of a heating cycle being performed in the chamber. Consequently, as shown in Figures 2 and 3, cooling device 60 can be movable towards and away from wafer 14. For example, base 62 as shown in Figure 1  
5 can include a mechanism which raises and lowers the cooling device at selected times.

For instance, cooling device 60 can be movable between a wafer nonengagement position as shown in Figure 2 and a wafer engagement position as shown in Figure 3. In the nonengagement position, cooling device 60 should be spaced from wafer 14 a distance sufficient so as to not interfere with the wafer as it is being heated. Once the wafer has been heated and needs to be cooled, however, cooling device 60 can be placed adjacent to the wafer as shown in Figure 3.  
10 Specifically, cooling device 60 can be placed directly in contact with the wafer or can be moved very close to the wafer without touching the wafer depending upon the particular application. When placed in the engagement position as shown in Figure 3, wafer 14 is  
15 rapidly cooled.

It should be understood, however, that besides cooling device 60 being movable towards and away from the wafer, alternatively, substrate holder 15 can be configured to move the wafer itself towards and away  
25 from the cooling device.

Further, besides adjusting the position of the cooling device in relation to the wafer, other controls can be used to selectively cool wafers according to the present invention. For instance, the flow of a cooling fluid through cooling channels 66 of cooling device 60 can be adjusted depending upon the amount of cooling that is desired at any particular time. For instance, when cooling is not desired, the  
30 flow of a cooling fluid to cooling device 60 can be  
35

slowed or stopped. Conversely, when it is desired to cool the wafer, the flow of a cooling fluid can be increased through the cooling device. In one embodiment, system controller 50 as shown in Figure 1 5 can be placed in communication with cooling device 60 for automatically adjusting the position of the cooling device and/or controlling the flow of a cooling fluid to a device.

Cooling member 64 of cooling device 60 can be 10 made from various materials. In particular, cooling member 64 should be made from a conductive material that acts as a heat exchanger between the cooling fluid and semiconductor wafer 14. Various materials that may be used to construct cooling member 64 15 include, for instance, a metal, such as aluminum, stainless steel or brass. This metal may be coated to prevent contamination between it and the semiconductor wafer.

Referring to Figure 4, an alternative embodiment 20 of a heating device 60 that may be used in the apparatus and process of the present invention is illustrated. Similar to the embodiment illustrated in Figures 2 and 3, in this embodiment, heating device 60 includes a cooling member 64 that defines one or more 25 cooling channels 66 for circulating a cooling fluid, such as a liquid. In this embodiment, however, cooling member 64 further defines at least one gas passage 68.

Gas passage 68 is designed to be connected to a 30 gas source that circulates a gas through cooling device 60. As shown, gas passage 68 flows through cooling member 64 and then includes a plurality of exits that release a gas adjacent to semiconductor wafer 14. In this manner, a gas being fed through gas 35 passage 68 is cooled by a cooling fluid being

circulated through channel 66 and is then directed towards semiconductor wafer 14 for cooling the wafer. The gas being fed through gas passage 68 should be an inert gas so that no undesired chemical reactions occur. For instance, molecular nitrogen, argon or helium can be used as the cooling gas.

In the embodiment illustrated in Figure 4, cooling device 60 can be stationary or can be movable similar to the embodiment illustrated in Figures 2 and 10 3. Preferably, in order to selectively cool wafers within a thermal processing chamber, the flow of the cooling gas into gas passage 68 should be controllable so that the gas flow can be stopped and started at desired times. In this regard, system controller 50 15 as shown in Figure 1 can be placed in communication with the cooling gas source and can be designed to control the flow of the cooling gas from the gas source to cooling device 60.

It should be understood that besides the 20 embodiments illustrated in the figures, cooling device 60 can be cooled in various other ways. For instance, in an alternative embodiment, an active cooling structure can be placed adjacent to or can be attached to cooling device 60 for cooling the device through 25 conduction. Alternatively, cooling device 60 can include a cooling member made from a thermoelectric material which maintains the cooling member at a lower temperature.

As described above, the purpose of cooling device 30 60 is to rapidly cool wafers in thermal processing chambers in order to increase the speed at which heating cycles can be performed on wafers in the chamber. Referring to Figure 5, for comparative purposes, a conventional heating cycle (a) is shown in 35 comparison to a heating cycle (b) that can be produced

using the apparatus of the present invention. As shown, the cooling rate using the apparatus of the present invention is dramatically increased. Of course, the graph illustrated in Figure 5 is for exemplary purposes only. It should be understood that with the cooling device of the present invention, the rate of cooling can be controlled such that any desired cooling curve can be followed.

For most applications, however, the cooling device of the present invention will be used to cool wafers as rapidly as possible. By cooling wafers rapidly, various advantages will result. For instance, besides reducing the amount of time it will take to process wafers, less undesirable chemical and physical reactions will occur during the cool down phase of the heating cycle.

These and other modifications and variations to the present invention may be practiced by those of ordinary skill in the art, without departing from the spirit and scope of the present invention, which is more particularly set forth in the appended claims. In addition, it should be understood that aspects of the various embodiments may be interchanged both in whole or in part. Furthermore, those of ordinary skill in the art will appreciate that the foregoing description is by way of example only, and is not intended to limit the invention so further described in such appended claims.
